## SPARSE MATRIX

### Overview

A matrix is represented as 2 dimensional array where every element is accessed by row and column index. Real world data such as image, spectrogram and graph can be modelled using matrices.

A matrix for which most of values are zero is termed as the sparse matrix. If a sparse matrix is stored in a memory as a two dimensional matrix it wastes lot of space.

So alternate representations are preferred for sparse matrix

Alternate representations are:

- Triple notation
- Linked representation

### Representations

#### 1. Triple notation

In triple notation sparse matrix is represented as an array of tuple values. Each tuple consists of

<rowno columnno Value>

The first block in array block holds information regarding

<total no of rows, total no of columns ,value>

Declaration

```
typedef struct
```

```
{
```

```
    int col;
```

```
    int row;
```

```
    int value;
```

```
} term;
```

```
term a[10];
```

Various operations that can be performed on sparse matrix are

Create\_SparseMatrix()

Transpose\_of\_SparseMatrix()

Add\_SparseMatrices()

## Multiple\_SparseMatrices()

$$\begin{bmatrix} 2 & 0 & 0 & 0 \\ 4 & 0 & 0 & 3 \\ 0 & 0 & 0 & 0 \\ 8 & 0 & 0 & 1 \\ 0 & 0 & 6 & 0 \end{bmatrix}$$

### Triple Notation

Row No	Column No	Value
5	4	6
0	0	2
1	0	4
1	3	3
3	0	8
3	3	1
4	2	6

## 2. Linked Representation

Two types of nodes are used

### Header Node

next	
down	right

### Data Node

row	col	value
down		right

```
#define MAX_SIZE 50 /* size of largest matrix */
typedef enum {head, entry} tagfield;
typedef struct matrixNode * matrixPointer;
typedef struct entryNode {
    int row;
    int col;
    int value; };
typedef struct matrixNode {
    matrixPointer down;
    matrixPointer right;
    tagfield tag;
    union
    {
        matrixPointer next;
        entryNode entry;
    } u;
};
```

$$\begin{bmatrix} 2 & 0 & 0 & 0 \\ 4 & 0 & 0 & 3 \\ 0 & 0 & 0 & 0 \\ 8 & 0 & 0 & 1 \\ 0 & 0 & 6 & 0 \end{bmatrix}$$

Sparse Matrix representation using Linked Nodes
