Department of Computer Science and Engineering

## Unit – 2 Application Layer

2.1 Principles of Network Applications

2.2 Web, HTTP and HTTPS

**2.3 The Domain Name System**

2.4 P2P Applications

2.5 Socket Programming with TCP & UDP

2.6 Other Application Layer Protocols

# COMPUTER NETWORKS

## DNS: Domain Name System

---

*people:* many identifiers:

- SSN, name, passport #

*Internet hosts, routers:*

- IP address (32 bit) - used for addressing datagrams
- “name”, e.g., cs.umass.edu - used by humans

Q: how to map between IP address and name, and vice versa ?

### *Domain Name System:*

- *distributed database*  
implemented in hierarchy of many *name servers*
- *application-layer protocol:*  
hosts, name servers  
communicate to *resolve* names  
(address/name translation)
  - note: core Internet function,  
*implemented as application-layer protocol*
  - complexity at network’s  
“edge”

# COMPUTER NETWORKS

## DNS: Services, Structure

### DNS services

- hostname to IP address translation
- host aliasing
  - canonical, alias names
- mail server aliasing
- load distribution
  - replicated Web servers: many IP addresses correspond to one name

[www.abc.example.com](http://www.abc.example.com) -> Canonical Host Name

[www.example.com](http://www.example.com) -> Alias Name

### *Q: Why not centralize DNS?*

- single point of failure
- traffic volume
- distant centralized database
- maintenance

[www.abc.example.com](http://www.abc.example.com) ->

Canonical Host Name

[bob@example.com](mailto:bob@example.com) ->

Alias Name

### *A: doesn't scale!*

- Comcast DNS servers alone: 600B DNS queries per day

# COMPUTER NETWORKS

## DNS: a distributed, hierarchical database

*Root*

*Top Level Domain*

*Authoritative*

Client wants IP address for [www.amazon.com](http://www.amazon.com); 1<sup>st</sup> approximation:

- client queries root server to find .com DNS server
- client queries .com DNS server to get amazon.com DNS server
- client queries amazon.com DNS server to get IP address for [www.amazon.com](http://www.amazon.com)

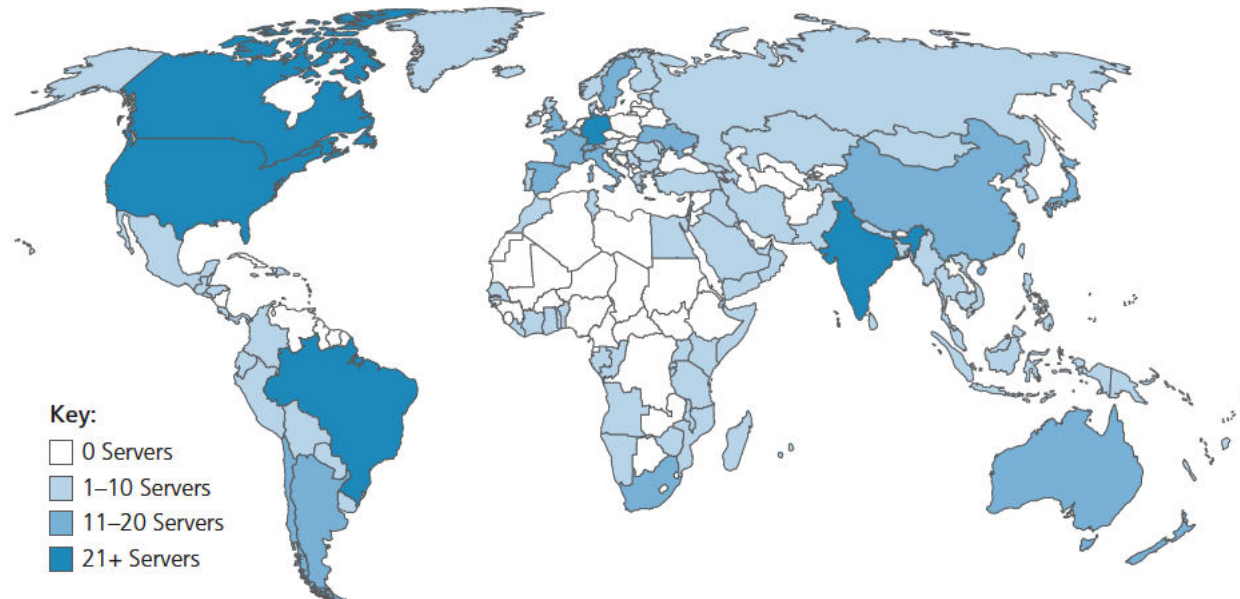

- DNS is organized according to zones.
  - A zone groups contiguous domains and subdomains on the domain tree.
  - Assign management authority to an entity.
- 
- The tree structure depicts subdomains within example.com domain.
  - Multiple DNS zones one for each country. The zone keeps records of who the authority is for each of its subdomains.
  - The zone for example.com contains only the DNS records for the hostnames that do not belong to any subdomain like mail.example.com

# COMPUTER NETWORKS

## DNS: root name servers

- official, contact-of-last-resort by name servers that can not resolve name
- *incredibly important* Internet function
  - Internet couldn't function without it!
  - DNSSEC – provides security (authentication and message integrity)
- ICANN (Internet Corporation for Assigned Names and Numbers) manages root DNS domain

13 logical root name “servers”  
worldwide each “server” replicated  
many times (~200 servers in US)

### Top-Level Domain (TLD) servers:

- responsible for .com, .org, .net, .edu, .aero, .jobs, .museums, and all top-level country domains, e.g.: .cn, .uk, .fr, .ca, .jp
- Network Solutions: authoritative registry for .com, .net TLD
- Educause: .edu TLD

### Authoritative DNS servers:

- organization's own DNS server(s), providing authoritative hostname to IP mappings for organization's named hosts
- can be maintained by organization or service provider

- does not strictly belong to hierarchy
- each ISP (residential ISP, company, university) has one
  - also called “default name server”
- when host makes DNS query, query is sent to its local DNS server
  - has local cache of recent name-to-address translation pairs (but may be out of date!)
  - acts as proxy, forwards query into hierarchy

**THANK YOU**
