DESIGN AND ANALYSIS OF ALGORITHMS
Question Bank (Unit 5)

PES University

- **Dynamic Programming**

- What does dynamic programming have in common with divide-and-conquer? What is a principal difference between them?
- The coin change problem does not have an optimal greedy solution in all cases (ex: coins 1,20,25 and amount 40). Is there a dynamic programming based algorithm that can solve all cases of the coin change problem?

- **The Knapsack Problem**

- Write pseudocode of the bottom-up dynamic programming algorithm for the knapsack problem
- True or False:
 1. A sequence of values in a row of the dynamic programming table for the knapsack problem is always nondecreasing?
 2. A sequence of values in a column of the dynamic programming table for the knapsack problem is always nondecreasing?

- **Memory Function Knapsack**

- Consider the use of the MF technique to compute binomial coefficient using the recurrence

$$C(n, k) = C(n - 1, k - 1) + C(n - 1, k)$$

- * How many table entries are filled?
- * How many are reused?

- **Transitive Closure (Warshall's Algorithm)**

- Is Warshall's algorithm efficient for sparse graphs? Why / why not?
- Can Warshall's algorithm be used to determine if a graph is a DAG (Directed Acyclic Graph)? If so, how?
- **All Pairs Shortest Path (Floyd's Algorithm)**
 - Give an example of a graph with negative weights for which Floyd's algorithm does not yield the correct result
 - Enhance Floyd's algorithm so that shortest paths themselves, not just their lengths, can be found
- **Optimal Binary Search Trees**
 - Space: $\Theta(n^2)$
 - Time: $\Theta(n^3)$, can be reduced to $\Theta(n^2)$ by exploiting monotonicity of entries in root table ($R[i, j]$ is always between $R[i, j - 1]$ and $R[i + 1, j]$)
 - Method can be expanded to include unsuccessful searches
- **Lower-Bound Arguments**
 - Prove that the classic recursive algorithm for the Tower of Hanoi puzzle makes the minimum number of disk moves
 - Find a trivial lower-bound class and indicate if the bound is tight:
 - * finding the largest element in an array
 - * generating all the subsets of an n -element set
 - * determining whether n given real numbers are all distinct
- **Decision Trees**
 - Consider the problem of finding the median of a three-element set a, b, c of orderable items
 - * What is the information-theoretic lower bound for comparison-based algorithms solving this problem?
 - * Draw a decision tree for an algorithm solving this problem
 - * Is the above bound tight?
