Input Enhancement in String Matching

### **Bharathi R**

Department of Computer Science & Engineering

### **String Matching**

String matching requires finding an occurrence of a given string of *m* characters called the *pattern* in a longer string of *n* characters called the *text*.

$$t_0 \quad \dots \quad t_i \quad \dots \quad t_{i+j} \quad \dots \quad t_{i+m-1} \quad \dots \quad t_{n-1}$$

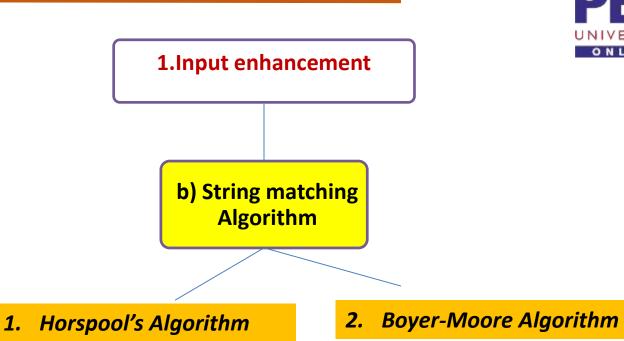

$$\downarrow \qquad \qquad \downarrow \qquad$$

# **Design and Analysis of Algorithms Input Enhancement in String Matching**

### Input-enhancement idea:

Preprocess the pattern to get some information about it, store this information in a table, and then use this information during an actual search for the pattern in a given text.

# Design and Analysis of Algorithms String matching by Brute force

**pattern**: a string of m characters to search for

text: a (long) string of n characters to search in

### **Brute force algorithm**

**Step 1** Align pattern at beginning of text

- **Step 2** Moving from left to right, compare each character of pattern to the corresponding character in text until either all characters are found to match (successful search) or a mismatch is detected
- **Step 3** While a mismatch is detected and the text is not yet exhausted, realign pattern one position to the right and repeat Step 2

Time complexity (worst-case): O(mn)

# Design and Analysis of Algorithms String matching by preprocessing

Several string searching algorithms are based on the input enhancement idea of preprocessing the pattern

- 1. Knuth-Morris-Pratt (KMP) algorithm preprocesses pattern left to right to get useful information for later searching
- 2. Boyer -Moore algorithm preprocesses pattern right to left and store information into two tables
- 3. Horspool's algorithm simplifies the Boyer-Moore algorithm by using just one table

# Design and Analysis of Algorithms Horspool's Algorithm

A simplified version of Boyer-Moore algorithm:

Preprocesses pattern to generate a "shift table" that determines how much to shift the pattern when a mismatch occurs

Always makes a shift based on the text's character  $\bf c$  aligned with the <u>last</u> compared (mismatched) character in the pattern according to the shift table's entry for  $\bf c$ 

# Design and Analysis of Algorithms How far to shift?

Look at first (rightmost) character in text that was compared:

	ok at hist (lighthlost) character in text that was compar
1.	The character is not in the pattern
	c (c not in pattern)
	≠ BAOBAB
	The character is in the pattern (but not the rightmost)O(O occurs once in pattern) BAOBAB
Е	A (A occurs twice in pattern) BAOBAB
_	The rightmost characters do matchB

# **Design and Analysis of Algorithms Shift Table**

Shift sizes can be precomputed by the formula

$$t(c) = \begin{cases} \text{the pattern's length } m, \\ \text{if } c \text{ is not among the first } m-1 \text{ characters of the pattern;} \\ \text{the distance from the rightmost } c \text{ among the first } m-1 \text{ characters of the pattern to its last character, otherwise.} \end{cases}$$

By scanning pattern before search begins and stored in a table called **shift table**. After the shift, the right end of pattern is t(c) positions to the right of the last compared character in text.

Shift table is indexed by text and pattern alphabet Eg: for **BAOBAB**:

A	В	С	D	E	F	G	н	I	J	K	L	M	N	0	P	Q	R	S	Т	U	V	W	X	Y	Z
1	2	6	6	6	6	6	6	6	6	6	6	6	6	3	6	6	6	6	6	6	6	6	6	6	6

# **Design and Analysis of Algorithms Shift Table**

```
t(c) = \begin{cases} \text{the pattern's length } m, \\ \text{if } c \text{ is not among the first } m-1 \text{ characters of the pattern;} \end{cases}
t(c) = \begin{cases} \text{the pattern's length } m, \\ \text{the distance from the rightmost } c \text{ among the first } m-1 \text{ characters of the pattern to its last character, otherwise.} \end{cases}
```

# ALGORITHM Shift Table (P[0..m-1]) //Fills the shift table used by Horspool's and Boyer-Moore algorithms //Input: Pattern P[0..m-1] and an alphabet of possible characters //Output: Table[0..size-1] indexed by the alphabet's characters and filled with shift sizes computed by formula (7.1) for $i \leftarrow 0$ to size-1 do $Table[i] \leftarrow m$ for $j \leftarrow 0$ to m-2 do $Table[P[j]] \leftarrow m-1-j$ return Table

### **Horspool Matching**

```
HorspoolMatching(P[0..m-1], T[0..n-1])
ALGORITHM
    //Implements Horspool's algorithm for string matching
    //Input: Pattern P[0..m-1] and text T[0..n-1]
    //Output: The index of the left end of the first matching substring
              or -1 if there are no matches
    ShiftTable(P[0..m-1]) //generate Table of shifts
    i \leftarrow m-1
                             //position of the pattern's right end
    while i \le n-1 do
        k \leftarrow 0
                                 //number of matched characters
        while k \le m - 1 and P[m - 1 - k] = T[i - k] do
            k \leftarrow k + 1
        if k = m
            return i-m+1
        else i \leftarrow i + Table[T[i]]
    return -1
```

## **Horspool Matching -Example**

$$s_0 \dots s_{n-1}$$
BARBER

character c	Α	В	С	D	Е	F		R		Z	_
shift $t(c)$	4	2	6	6	1	6	6	3	6	6	6

# **Example of Horspool's algorithm**

A	В	С	D	E	F	G	Н	I	J	K	L	M	N	0	P	Q	R	S	T	U	V	W	X	Y	Z	_
1	2	6	6	6	6	6	6	6	6	6	6	6	6	3	6	6	6	6	6	6	6	6	6	6	6	6

BARD LOVED BANANAS BAOBAB

BAOBAB

BAOBAB

BAOBAB (unsuccessful search)
